

links 707

Links 707 is a new sand product that has been developed and tested for use in the construction and maintenance of golfing greens.

We have received positive feedback about the product from professionals within the turf industry including a number of courses who have been using the material on site.

Links 707 is a uniform medium-fine rootzone and topdressing sand similar in physical properties to the type of sand on which the game of golf originated in Scotland. It is a material that is best used in its own right as a pure sand growing medium rather than being pre-mixed with organic and/or soil amendments.

The saturated hydraulic conductivity of the sand measured under standard laboratory conditions is 600 mm/hr, well above the limit of 150 mm/hr recommended by the US Golf Association.

The depth of sand profile necessary to achieve a satisfactory air/water balance in the rootzone is typically 250-275 mm. Links 707 has a negligible calcium carbonate content.

Links 707 can be used in both 'California green' and 'sand-over-gravel' golf green construction systems.

We are happy to recommend experienced sports turf consultants to help you determine the best option for using Links 707 for your situation.

Availability:

Links 707 is available all year round in the Auckland region
